

# Introduction to SPIM

Computer Architecture 2018

2018/10/3

# Outline

- Introduction
- General Layout, MIPS Instruction and SPIM I/O
- Programming Example
- Homework

# Introduction to SPIM Simulator

- **Spim** is a self-contained simulator that runs **MIPS32** programs
- Developed by **James R. Larus**, Computer Science Department, University of Wisconsin-Madison
- **It only runs assembly code** but not executable binary program
- Homepage
  - <http://spimsimulator.sourceforge.net/>
  - [http://spimsimulator.sourceforge.net/HP\\_AppA.pdf](http://spimsimulator.sourceforge.net/HP_AppA.pdf)

# Install QtSpim

- Download from this webpage
  - <http://sourceforge.net/projects/spimsimulator/files/>

# Outline

- Introduction
- Program structure, MIPS Instructions and SPIM I/O
- Programming Example
- Homework

# Program Structure

- Plain text file with **data declarations**, **program code** (name of file should end in suffix .s to be used with SPIM simulator)
- **Data declarations** start with **.data** directive
  - Allocated in memory (DRAM)
  - Variables used in program
- **Program code** starts with **.text** directive
  - Starting point (**main**)
- **Comments**
  - **# anything you want**

```
exercise.s - 記事本
檔案(F) 編輯(E) 格式(O) 檢視(V) 說明(H)
# Comment giving name of program and description of function
# exercise.s
# Bare-bones outline of MIPS assembly language program

.data          # variable declarations follow this line
               # ...
var1:          .word    23

.text          # instructions follow this line

main:         # indicates start of code (first instruction to execute)
```

# Data declarations

- **.word, .half** - 32/16 bit integer
- **.byte** - 8 bit integer (similar to 'char' type in C)
- **.ascii, .asciiz** - string (asciiz is null terminated)
  - Strings are enclosed in double-quotes(")
  - Special characters in strings follow the C convention
  - newline(\n), tab(\t), quote(\")
- **.double, .float** - floating point
- **Format**
  - name:      storage\_type      value(s)
    - Create storage for variable of specified type with given name and specified value
    - Value(s) usually gives initial value(s); for storage type **.space**, gives number of spaces to be allocated (bytes)
    - For example,      `var1:                  .word    23`

# MIPS Instructions (**Load / Store Instructions**)

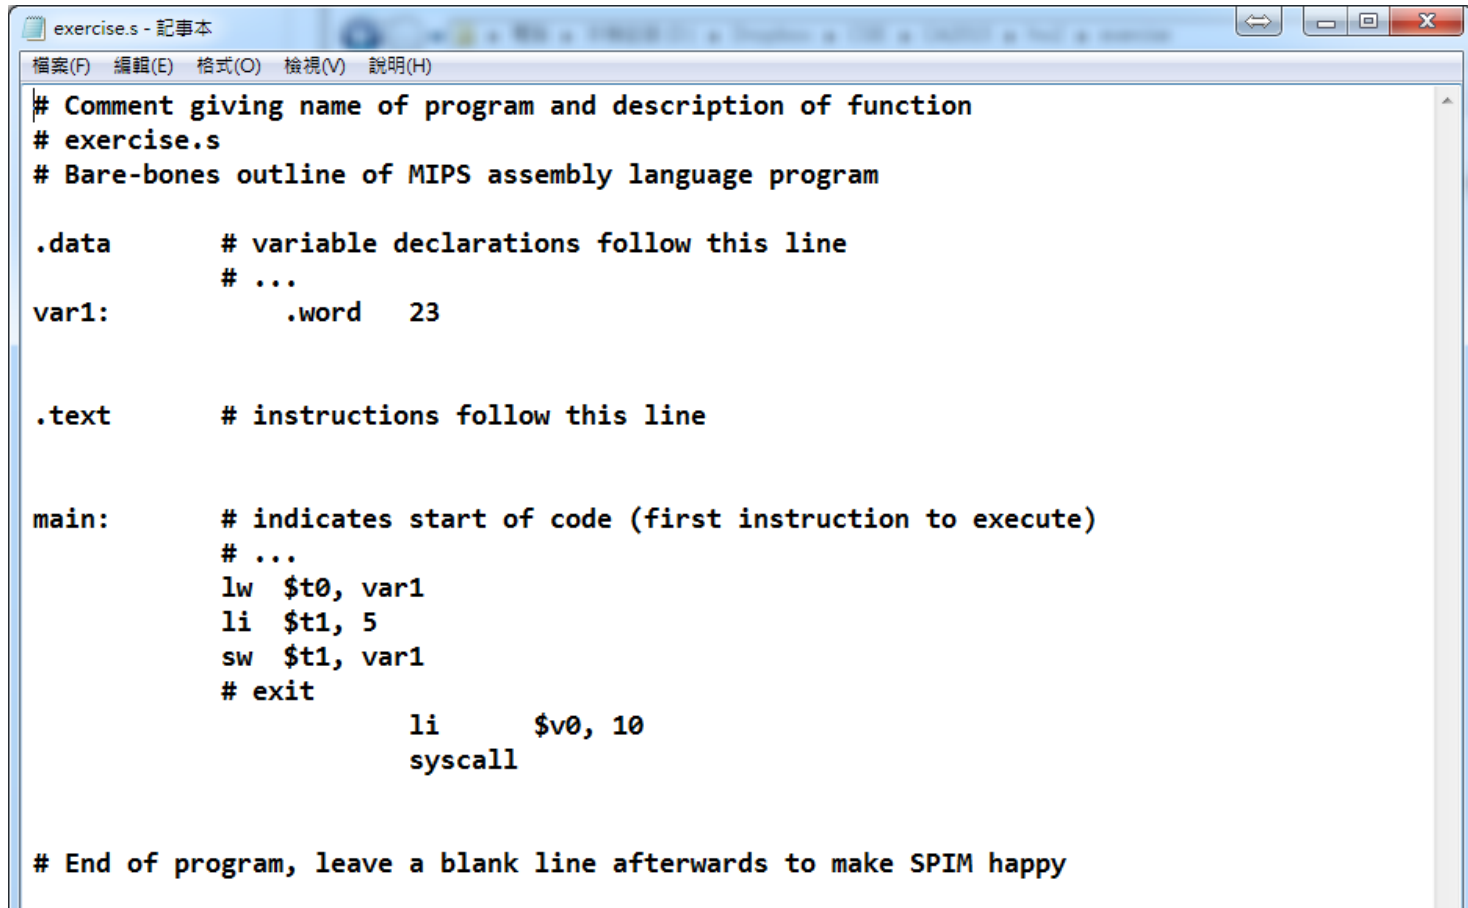

- RAM access only allowed with load and store instructions
  - All other instructions use register operands
- **Load**
  - **lw** **register\_destination, RAM\_source**
    - Copy **word** (4 bytes) at source RAM location to destination register
  - **lb** **register\_destination, RAM\_source**
    - Copy **byte** at source RAM location to low-order byte of destination register, and sign-e.g.tend to higher-order bytes

# MIPS Instructions (**Load / Store Instructions**)

- RAM access only allowed with load and store instructions
  - All other instructions use register operands
- **Store**
  - **sw** **register\_source, RAM\_destination**
    - Store **word** in source register into RAM destination
  - **sb** **register\_source, RAM\_destination**
    - Store **byte** (low-order) in source register into RAM destination
- **load immediate**
  - **li** **register\_destination, value**
    - load **immediate value** into destination register

# MIPS Instructions (Load / Store Instructions)

- Example

```
exercise.s - 記事本
檔案(F) 編輯(E) 格式(O) 檢視(V) 說明(H)

# Comment giving name of program and description of function
# exercise.s
# Bare-bones outline of MIPS assembly language program

.data          # variable declarations follow this line
               # ...
var1:          .word    23

.text          # instructions follow this line

main:          # indicates start of code (first instruction to execute)
               # ...
               lw  $t0, var1
               li  $t1, 5
               sw  $t1, var1
               # exit
               li   $v0, 10
               syscall

# End of program, leave a blank line afterwards to make SPIM happy
```

# MIPS Instructions (Load / Store Instructions)

- Example

The image shows a MIPS assembly program in a text editor window titled "exercise.s - 記事本". The program includes comments, variable declarations, and instructions. A red arrow points from the value 23 in the assembly code to the memory layout window.

```
# Comment giving name of program and description of function
# exercise.s
# Bare-bones outline of MIPS assembly language program

.data      # variable declarations follow this line
# ...
var1:      .word   23

.text      # instructions follow this line

main:      # indicates start of code (first instruction to execute)
# ...
lw  $t0, var1
li  $t1, 5
sw  $t1, var1
# exit
      li    $v0, 10
      syscall

# End of program, leave a blank line afterwards to make SPIM happy
```

The memory layout window shows the "Data" segment. It displays the "User data segment" from address 10000000 to 10040000. The layout includes memory ranges and their contents:

Memory Range	Content
[10000000]..[1000ffff]	00000000
[10010000]	00000017 00000000 00000000 00000000
[10010010]..[1003ffff]	00000000

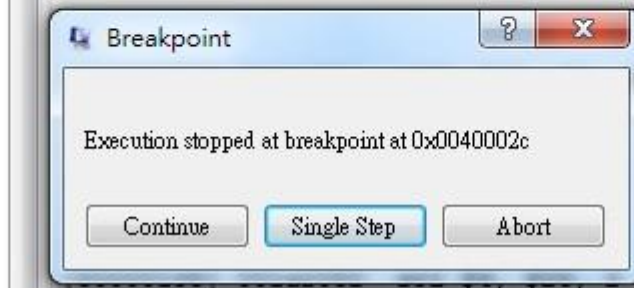

A red arrow points from the value 23 in the assembly code to the memory layout window, indicating the address where the variable var1 is stored.

# MIPS Instructions (Load / Store Instructions)

- Example
  - lw \$t0, var1

```
R0 [r0] = 0
R1 [at] = 10010000

```

Data	Text			
Data				
User data segment [10000000]..[10040000]				
[10000000]..[1000ffff]	00000000			
[10010000]	00000005	00000000	00000000	00000000
[10010010]..[1003ffff]	00000000			

# MIPS Instructions (Indirect and Based Addressing)

- **Load address**

- **la**            **\$t0, var1**

- Copy RAM address of var1 (presumably a label defined in the program) into register \$t0

- **Indirect addressing**

- **lw**            **\$t2, (\$t0)**

- load word at RAM address contained in \$t0 into \$t2

- **sw**            **\$t2, (\$t0)**

- store word in register \$t2 into RAM at address contained in \$t0

# MIPS Instructions (Indirect and Based Addressing)

- **Based or indexed addressing:**
  - **lw            \$t2, 4(\$t0)**
    - load word at RAM address ( $\$t0+4$ ) into register \$t2
    - "4" gives offset from address in register \$t0
  - **sw            \$t2, -12(\$t0)**
    - store word in register \$t2 into RAM at address ( $\$t0 - 12$ )
    - negative offsets are fine

# MIPS Instructions (Indirect and Based Addressing)

```
.data          # variable declarations follow this line
               # ...
array1: .space    10

.text          # instructions follow this line

main:         # indicates start of code (first instruction to execute)
               # ...
               la    $t0, array1
               li    $t2, 10
               li    $t1, 1

loop:
               sb    $t1, ($t0)
               addi  $t0, $t0, 1
               addi  $t1, $t1, 1
               ble   $t1, $t2, loop
               # exit

exit:
               li    $v0, 10
               syscall
```

Data	Text
Data	
User data segment [10000000]..[10040000]	
[10000000]..[1000ffff]	00000000
[10010000]	04030201 08070605 00000a09 00000000 . . . . .
[10010010]..[1003ffff]	00000000

**Note:** Based addressing is especially useful for:

- Arrays
  - Access elements as offset from base address
- Stacks
  - Easy to access elements at offset from stack pointer or frame pointer

# MIPS Instructions (Arithmetic Instructions)

- Operand size is **word** (4 bytes)

<b>add \$t0,\$t1,\$t2</b>	<b>\$t0 = \$t1 + \$t2; add as signed (2's complement) integers</b>
<b>sub \$t2,\$t3,\$t4</b>	<b>\$t2 = \$t3 - \$t4</b>

<b>bne \$t0,\$t1,target</b>	<b>branch to target if \$t0 &lt;&gt; \$t1</b>

- **Jumps**

<b>j target</b>	<b>unconditional jump to program label target</b>
<b>jr \$t3</b>	<b>jump to address contained in \$t3 ("jump register")</b>

# MIPS Instructions (Control Structures)

- MIPS

Jump	j	J	PC=JumpAddr
Jump And Link	jal	J	R[31]=PC+8;PC=JumpAddr
Jump Register	jr	R	PC=R[rs]

- RISC-V

jal	UJ	Jump & Link	$R[rd] = PC+4; PC = PC + \{imm, 1b'0\}$
jalr	I	Jump & Link Register	$R[rd] = PC+4; PC = R[rs1] + imm$
lb	I	Load Byte	$R[rd] = \{56'bM[] (7), M[R[rs1] + imm] (7:0)\}$

# MIPS Instructions (Control Structures)

- **Control flow in MIPS**
  - Subroutine/function Calls
  - A, B & C functions

1. Someone calls A
2.     A calls B
3.         B calls C
4.         C returns to B
5.     B returns to A
6. A returns

# Control flow in C

- Invoking a function changes the control flow of a program **twice**.
  - **Calling** the function
  - **Returning** from the function
- In this example the main function calls fact twice, and fact returns twice—but to different locations in main.
- Each time fact is called, the CPU has to remember the appropriate return address.

```
int main()
{
    ...
    t1= fact(8);
    t2= fact(3);
    t3= t1+t2;
    ...
}

int fact(int a0)
{
    int t1, v0 = 1;
    for(t1 = a0; t1 > 1; t1--)
        v0 = v0 * t1;
    return v0;
}
```

# Control flow in MIPS

- MIPS uses the jump-and-link instruction **jal** to call functions.
  - The jal saves the return address (the address of the next instruction) in the dedicated register \$ra, before jumping to the function.
  - jal is the only MIPS instruction that can access the value of the program counter, so it can store the return address PC+4 in \$ra.

## jal fact

- To transfer control back to the caller, the function just has to jump to the address that was stored in \$ra.

## jr \$ra

**Note:** return address stored in register \$ra; if subroutine will call other subroutines, or is recursive, return address should be copied from \$ra onto stack to preserve it, since jal always places return address in this register and hence will overwrite previous value

# Function calls and stacks

- Notice function calls and returns occur in a stack-like order: the most recently called function is the first one to return.

1. Someone calls A
2. A calls B
3. B calls C
4. C returns to B
5. B returns to A
6. A returns

- Here, for example, C must return to B before B can return to A.

# Register

Register name	Number	Usage
\$zero	0	constant 0
\$at	1	reserved for assembler
\$v0	2	expression evaluation and results of a function
\$v1	3	expression evaluation and results of a function
\$a0	4	argument 1
\$a1	5	argument 2
\$a2	6	argument 3
\$a3	7	argument 4
\$t0	8	temporary (not preserved across call)
\$t1	9	temporary (not preserved across call)
\$t2	10	temporary (not preserved across call)
\$t3	11	temporary (not preserved across call)
\$t4	12	temporary (not preserved across call)
\$t5	13	temporary (not preserved across call)
\$t6	14	temporary (not preserved across call)
\$t7	15	temporary (not preserved across call)

Results  
(\$v0, \$v1)

Function parameters  
(\$a0, \$a1, \$a2, \$a3)

→ The usage description of these registers are just “convention”. They are physically the same.

# Register

\$s0	16	saved temporary (preserved across call)
\$s1	17	saved temporary (preserved across call)
\$s2	18	saved temporary (preserved across call)
\$s3	19	saved temporary (preserved across call)
\$s4	20	saved temporary (preserved across call)
\$s5	21	saved temporary (preserved across call)
\$s6	22	saved temporary (preserved across call)
\$s7	23	saved temporary (preserved across call)
\$t8	24	temporary (not preserved across call)
\$t9	25	temporary (not preserved across call)
\$k0	26	reserved for OS kernel
\$k1	27	reserved for OS kernel
\$gp	28	pointer to global area
\$sp	29	stack pointer
\$fp	30	frame pointer
\$ra	31	return address (used by function call)

# SPIM I/O

- **SPIM** provides a small set of operating system-like services through the system call instruction.
- A program loads the system call code into register \$v0 and arguments into registers \$a0–\$a3 (or \$f12 for floating-point values).
- System calls that return values put their results in register \$v0 (or \$f0 for floating-point results).

# System Call

Service	System call code	Arguments	Result	
print_int	1	\$a0 = integer		move \$a0, \$s1 li \$v0, 1 syscall # print the result to consule
print_float	2	\$f12 = float		
print_double	3	\$f12 = double		
print_string	4	\$a0 = string		
read_int	5		integer (in \$v0)	li \$v0, 5 syscall # read a integer into \$v0
read_float	6		float (in \$f0)	
read_double	7		double (in \$f0)	
read_string	8	\$a0 = buffer, \$a1 = length

# Pseudo Instructions

- When machine code is generated, the pseudo instructions are converted to real instructions

`move $5, $3` → `add $5, $3, $0`

`neg $8, $9` → `sub $8, $0, $9`

`li $8, 44` → `addi $8, $0, 44` or `ori $8, $0, 44`

`blt $3, $4, dest` → `slt $1, $3, $4`  
`bne $1, $0, dest`

`bge $3, $4, dest` → `slt $1, $3, $4`  
`beq $1, $0, dest` `$3 >= $4` is the opposite of `$3 < $4`

`bgt $3, $4, dest` → `slt $1, $4, $3`  
`bne $1, $0, dest` `$3 > $4` same as `$4 < $3`

`ble $3, $4, dest` → `slt $1, $4, $3`  
`beq $1, $0, dest` `$3 <= $4` is the opposite of `$3 > $4`

# Example (Fibonacci Recurrence)

- Definition

$$\text{fib}(n) = \begin{cases} 0 & \text{if } n=0 \\ 1 & \text{if } n=1 \\ \text{fib}(n-1) + \text{fib}(n-2) & \text{otherwise} \end{cases}$$

- This is easy converse to a C program

```
int fib(int n)
{
    if (n <= 1)
        return n;
    else
        return fib(n-1) + fib(n-2);
}
```

# Example (Fibonacci Recurrence)

```
.data  
.text  
.globl main
```

```
main:
```

```
li $v0, 5  
syscall
```

Read integer from user  
and store in register \$v0

```
move $s0, $v0
```

Set argument \$a0

```
move $a0, $v0  
jal fib
```

Jump to Label fib and store  
next instruction program counter

```
move $a0, $v0
```

```
li $v0, 1  
syscall
```

Print integer result \$a0

```
li $v0, 10  
syscall
```

Exit program

# Example (Fibonacci Recurrence)

fib:

```
bgt $a0, 1, recurse  
move $v0, $a0  
jr $ra
```

```
if (n <= 1)  
    return n;
```

recurse:

```
sub $sp, $sp, 12  
sw $ra, 0($sp)  
sw $a0, 4($sp)
```

First save \$ra and the argument \$a0. An extra word is allocated on the stack to save the result of fib(n-1).

```
addi $a0, $a0, -1  
jal fib  
sw $v0, 8($sp)
```

The argument n is already in \$a0, so we can decrement it and then “jal fib” to implement the **fib(n-1)** call. The result is put into the stack.

```
lw $a0, 4($sp)  
addi $a0, $a0, -2  
jal fib
```

Retrieve n, and then call **fib(n-2)**.

```
lw $v1, 8($sp)  
add $v0, $v0, $v1
```

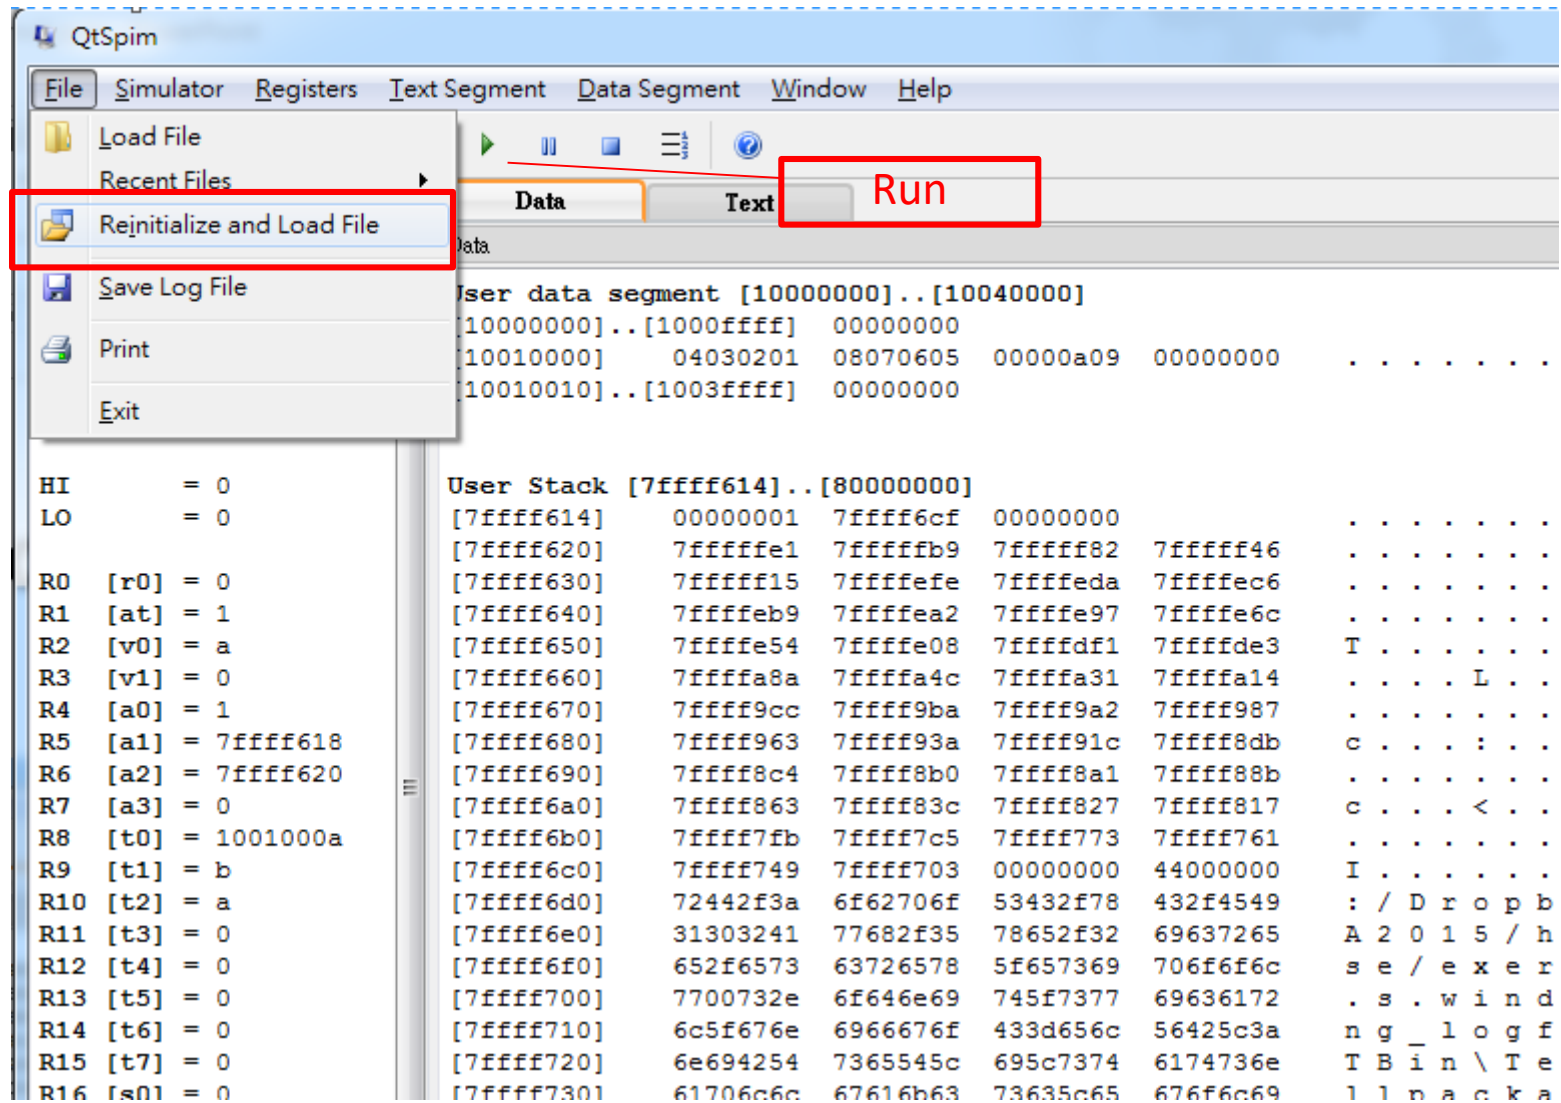

The results are summed and put in \$v0.

```
lw $ra, 0($sp)  
addi $sp, $sp, 12  
jr $ra
```

Retrieve return address and restore the stack pointer

# Debugger

- Register Window
- Breakpoint
- System call to console

# Outline

- Introduction
- General Layout, MIPS Instruction and SPIM I/O
- Programming Example
- Homework

# Homework2

- Simple Calculator
  - Write a MIPS32 assembly program to calculate two integers.
  - Read equation from an input file and output to an output file
  - Support "+", "-", "\*", "/" **integer** operations
  - Output "XXXX" and exit immediately when:
    - Unsupported operator (^, √, ...)
    - Divided by 0
  - You don't need to check if the input number is really an integer. (we won't test "1.1+2.3")

# Homework2

- Simple Calculator

- I/O Formats:

- Input format and an example:

<n1><operator><n2>

02+99

- Input filename "input.txt"
      - $0 \leq n1, n2 < 100, n1, n2 \in \mathbb{Z}$
      - All the number are two-digit
        - » 2(x) 02(o)
    - Output: print the result in a file named "output.txt"

0101

- $0 \leq \text{Output}$
        - Output filename "output.txt"
        - Four-digit positive number or "XXXX"

# Homework2

- Simple Calculator

- Modify from the "sample\_code.s"

- Make sure your program could do the right calculation
      - You should identify whether the operator is "+", "-", "\*" or "/"
    - Make sure your program satisfies the I/O formats
      - You should implement the function of "itoa"
    - Make sure your program read from & dump the result to the correct file before submission

- "input.txt" && "output.txt"

```
# TODO : change the file name/path to access the files
# NOTE : Before you submit the code, make sure these two fields are "input.txt" and "output.txt"
file_in:
    .ascii "input.txt"
file_out:
    .ascii "output.txt"
```

- Helpful tools in the sample code

- A file reader and writer already exist in the "sample\_code.s"
    - A function that pops outputs (integer) to console to help you debug.

# Homework2

- Submission
  - Due: 2018/10/16 (Tuesday) midnight (23:59:59)
  - Please upload to NTU COOL

"readme.txt":

大概說明一下

1. code 是怎麼實作
  2. 編寫的平台(Ex: Windows, Linux or Apple)
- 主要是批改有問題的時候助教會作為參考

- You should compress the folder in a .zip file
  - hw2\_<studentID>[\_v<version>].zip (ex. hw2\_r03922024\_v0.zip) (英文小寫)
    - hw2\_<studentID>
      - hw2\_<studentID>.s
      - readme.txt
